Outline

20	Cgroups: Introduction	20-1
20.1	Preamble	20-3
20.2	What are control groups?	20-9
20.3	An example: the <code>pids</code> controller	20-16
20.4	Creating, destroying, and populating a cgroup	20-20
20.5	Exercises	20-28
20.6	Enabling and disabling controllers	20-34
20.7	Exercises	20-49
20.8	Appendix: Systemd and cgroups	20-53

Goals

- We'll focus on:
 - General principles of operation; goals of cgroups
 - The `cgroup2` filesystem
 - Interacting with `cgroup2` filesystem using shell commands
 - Origin of cgroups v2 (i.e., problems with cgroups v1)
 - Differences between cgroups v2 and v1
- We'll look **briefly** at some of the controllers

- Kernel documentation files
 - V2: [Documentation/admin-guide/cgroup-v2.rst](#)
 - V1: [Documentation/admin-guide/cgroup-v1/*.rst](#)
 - Before Linux 5.3: [Documentation/cgroup-v1/*.txt](#)
- [cgroups\(7\)](#) manual page
- Chris Down, *7 years of cgroup v2* (FOSDEM 2023), <https://www.youtube.com/watch?v=LX6fM1IYZcg>
- Neil Brown's (2014) LWN.net series on cgroups: <https://lwn.net/Articles/604609/>
 - Thought-provoking ideas on the meaning of grouping & hierarchy
- <https://lwn.net/Articles/484254/> – Tejun Heo's initial thoughts about redesigning cgroups (Feb 2012)
 - See also <https://lwn.net/Articles/484251/>, *Fixing Control Groups*, Jon Corbet, Feb 2012
- Other articles at https://lwn.net/Kernel/Index/#Control_groups

man7.org

Some history

- 2006/2007, “Process Containers” @ Google ⇒ Cgroups v1
- Jan 2008: initial mainline kernel release (Linux 2.6.24)
 - Three resource controllers (all CPU-related) in initial release
- Subsequently, other controllers are added
 - [memory](#), [devices](#), [freezer](#), [net_cls](#), [blkio](#)...
- But a few years of uncoordinated design leads to a mess
 - Decentralized design fails us... again
- 2012: work has already begun on cgroups v2...

man7.org

Some history

- Sep 2015: *systemd* adds cgroup v2 support
 - (Based on kernel 4.2)
- Mar 2016: cgroups v2 officially released (Linux 4.5)
 - But, lacks feature parity with cgroups v1
- Jan 2018: *cpu* and *devices* controllers are released for cgroups v2
 - (Absence had been major roadblock to adoption of v2)
- Oct 2019: Fedora 31 is first distro to move to v2-by-default
- 2020: Docker 20.10 gets cgroups v2 support
- Later: other distros move to v2-by-default
 - 2021: Debian 11.0; Ubuntu 21.10; Arch
 - openSUSE (2024?)

We have passed the tipping point

- We have passed the v1-to-v2 tipping point:
 - *systemd*, Docker and other tools fully support cgroups v2, and the distros have migrated to v2
 - Cgroups v2 offers a number of advantages over v1
- ⇒ we'll focus on cgroups v2, and later look at how v1 is different

Outline

20	Cgroups: Introduction	20-1
20.1	Preamble	20-3
20.2	What are control groups?	20-9
20.3	An example: the <code>pids</code> controller	20-16
20.4	Creating, destroying, and populating a cgroup	20-20
20.5	Exercises	20-28
20.6	Enabling and disabling controllers	20-34
20.7	Exercises	20-49
20.8	Appendix: Systemd and cgroups	20-53

What are control groups?

- Two principal components:
 - A **mechanism for hierarchically grouping** processes
 - A set of **controllers** (kernel components) that manage, control, or monitor processes in cgroups
- Interface is via a pseudo-filesystem
- Cgroup manipulation takes form of filesystem operations, which might be done:
 - Via shell commands
 - Programmatically
 - Via management daemon, e.g., *systemd*
 - (See appendix)
 - Via your container framework's tools (e.g., LXC, Docker)

What do cgroups allow us to do?

- Limit resource usage of group
 - E.g., limit % of CPU available to group; limit amount of memory that group can use
- Resource accounting
 - Measure resources used by processes in group
- Limit device access
- Pin processes to CPU cores
- Shape network traffic
- Freeze a group
 - Freeze, restore, and checkpoint a group
- And more...

Terminology

- **Control group**: a group of processes that are bound together for purpose of resource management
- **(Resource) controller**: kernel component that controls or monitors processes in a cgroup
 - E.g., **memory** controller limits memory usage; **cpu** controller limits CPU usage
 - Also known as **subsystem**
 - (But that term is rather ambiguous because so generic)
- Cgroups are arranged in a **hierarchy**
 - Each cgroup can have zero or more child cgroups
 - Child cgroups **inherit** control settings from parent

Filesystem interface

- Cgroup filesystem **directory structure defines cgroups + cgroup hierarchy**
 - I.e., use `mkdir(2)` / `rmdir(2)` (or equivalent shell commands) to create cgroups
- Each **subdirectory contains automatically created files**
 - Some files are used to **manage the cgroup** itself
 - Other files are **controller-specific**
- Files in cgroup are used to:
 - **Define/display membership** of cgroup
 - **Control behavior** of processes in cgroup
 - **Expose information** about processes in cgroup (e.g., resource usage stats)

The cgroup2 filesystem

- On boot, `systemd` mounts v2 hierarchy at `/sys/fs/cgroup`
 - (or `/sys/fs/cgroup/unified`, if `systemd` is operating in cgroups “hybrid” mode)

```
# mount -t cgroup2 none /sys/fs/cgroup
```

- The (pseudo)filesystem type is “`cgroup2`”
 - In cgroups v1, filesystem type is “`cgroup`”
- The cgroups v2 mount is sometimes known as the “**unified hierarchy**”
 - Because all controllers are associated with a single hierarchy
 - By contrast, in v1 there were multiple hierarchies

Booting to cgroups v2

- You may be on a distro that uses *systemd*'s “hybrid” mode by default
 - Hybrid mode combines use of cgroups v1 and v2
- Problem: can't simultaneously use a controller in both v1 and v2
- Simplest solution is usually to reboot, so that *systemd* abandons its hybrid mode, and uses just v2
 - If this shows a value > 1 , then you need to reboot:

```
$ grep -c cgroup /proc/mounts      # Count cgroup mounts
```

- **Either:** use kernel boot parameter, *cgroup_no_v1*:
 - *cgroup_no_v1=all* $\Rightarrow$ disable all v1 controllers
- **Or:** use *systemd.unified_cgroup_hierarchy* boot parameter

man7.org

Outline

20	Cgroups: Introduction	20-1
20.1	Preamble	20-3
20.2	What are control groups?	20-9
20.3	An example: the <i>pids</i> controller	20-16
20.4	Creating, destroying, and populating a cgroup	20-20
20.5	Exercises	20-28
20.6	Enabling and disabling controllers	20-34
20.7	Exercises	20-49
20.8	Appendix: Systemd and cgroups	20-53

Example: the pids controller

- `pids` (“process number”) controller allows us to limit number of PIDs in cgroup (prevent `fork()` bombs!)
- Create new cgroup, and place shell’s PID in that cgroup:

```
# mkdir /sys/fs/cgroup/mygrp
# echo $$
17273
# echo $$ > /sys/fs/cgroup/mygrp/cgroup.procs
```

- `cgroup.procs` defines/displays PIDs in cgroup
- (Note ‘#’ prompt $\Rightarrow$ all commands done as superuser)
- Moving a PID into a group automatically removes it from group of which it was formerly a member
 - I.e., a process is always a member of exactly one group in the hierarchy

man7.org

Example: the pids controller

- Can read `cgroup.procs` to see PIDs in group:

```
# cat /sys/fs/cgroup/mygrp/cgroup.procs
17273
20591
```

- Where did PID 20591 come from?
- PID 20591 is `cat` command, created as a child of shell
 - Child process inherits cgroup membership from parent
- `pids.current` shows how many processes are in group:

```
# cat /sys/fs/cgroup/mygrp/pids.current
2
```

- Two processes: shell + `cat`

man7.org

Example: the pids controller

- We can limit number of PIDs in group using `pids.max` file:

```
# echo 5 > /sys/fs/cgroup/mygrp/pids.max
# for a in $(seq 1 5); do sleep 60 & done
[1] 21283
[2] 21284
[3] 21285
[4] 21286
bash: fork: retry: Resource temporarily unavailable
bash: fork: retry: Resource temporarily unavailable
bash: fork: retry: Resource temporarily unavailable
bash: fork: Resource temporarily unavailable
```

- (The shell retries a few times and then gives up)
- `pids.max` defines/exposes limit on number of PIDs in cgroup
- From a **different** shell, examine `pids.current`:

```
$ cat /sys/fs/cgroup/mygrp/pids.current
5
```

- Not possible from first shell (can't create more processes)

man7.org

Outline

20	Cgroups: Introduction	20-1
20.1	Preamble	20-3
20.2	What are control groups?	20-9
20.3	An example: the <code>pids</code> controller	20-16
20.4	Creating, destroying, and populating a cgroup	20-20
20.5	Exercises	20-28
20.6	Enabling and disabling controllers	20-34
20.7	Exercises	20-49
20.8	Appendix: Systemd and cgroups	20-53

Creating cgroups

- Initially, all processes on system are members of **root cgroup**
- New cgroups are **created** by creating subdirectories under cgroup mount point:

```
# mkdir /sys/fs/cgroup/mygrp
```

- Relationships between cgroups are reflected by creating nested (arbitrarily deep) subdirectory structure

Destroying cgroups

An **empty cgroup** can be **destroyed** by removing directory

- **Empty** == last process in cgroup terminates or migrates to another cgroup **and** last child cgroup is removed
 - Presence of zombie process does **not** prevent removal of cgroup directory
 - (Notionally, zombies are moved to root cgroup)
- Not necessary (or possible) to delete attribute files inside cgroup directory before deleting it

Placing a process in a cgroup

- To move a **process** to a cgroup, we write its PID to `cgroup.procs` file in corresponding subdirectory

```
# echo $$ > /sys/fs/cgroup/mygrp/cgroup.procs
```

- In multithreaded process, moves all threads to cgroup
- ⚠ Can write only one PID at a time
 - Otherwise, `write()` fails with `EINVAL`

Viewing cgroup membership

- **To see PIDs in cgroup**, read `cgroup.procs` file
 - PIDs are newline-separated
 - Zombie processes do not appear in list
- ⚠ List is **not guaranteed to be sorted or free of duplicates**
 - PID might be moved out and back into cgroup or recycled while reading list

Cgroup membership details

- A **process can be member of just one cgroup**
 - That association defines attributes / parameters that apply to the process
- Adding a process to a different cgroup automatically removes it from previous cgroup
- On `fork()`, **child inherits cgroup membership(s)** of parent
 - Afterward, cgroup membership(s) of parent and child can be independently changed
 - Since Linux 5.7 (2020), a child process can be created in a specific v2 cgroup using `clone3()` `CLONE_INTTO_CGROUP`
 - See `procexec/t_CLONE_INTTO_CGROUP.c`

/proc/PID/cgroup file

- `/proc/PID/cgroup` shows cgroup memberships of PID

```
8:cpu,cpuacct:/cpugrp3
7:freezer:/
...
0::/grp1
```

- ① Hierarchy ID (0 for v2 hierarchy)
 - Can be matched to hierarchy ID in another file, `/proc/cgroups` (but that file is not so interesting)
 - ② Comma-separated list of controllers bound to the hierarchy
 - Field is empty for v2 hierarchy
 - ③ Pathname of cgroup to which this process belongs
 - Pathname is relative to cgroup root directory
- On a system booted in v2-only mode, there is just one line in this file (`0::...`)

Killing all processes in a cgroup

- Writing “1” to `cgroup.kill` kills all processes in a cgroup
 - Action is recursive
 - I.e., processes in descendant cgroups are also killed
 - Processes are killed using `SIGKILL`
 - File is write-only, and available only in non-root cgroups :-)
- Available since Linux 5.14 (2021)
- Example use cases:
 - Service managers (e.g., `systemd`) can kill all processes in a service
 - User-space “out-of-memory” (OOM) handlers can quickly/easily kill an entire cgroup
 - Handle some kill-container use cases that can’t be handled by killing container PID 1

man7.org

Notes for online practical sessions

- Small groups in **breakout rooms**
 - Write a note into Slack if you have a preferred group
- **We will go faster, if groups collaborate** on solving the exercise(s)
 - You can **share a screen** in your room
- I will circulate regularly between rooms to answer questions
- Zoom has an “**Ask for help**” button...
- **Keep an eye on the #general Slack channel**
 - Perhaps with further info about exercise;
 - Or a note that the exercise merges into a break
- When your room has finished, write a message in the Slack channel: “******* Room X has finished *******”
 - Then I have an idea of how many people have finished

man7.org

Shared screen etiquette

- It may help your colleagues if you **use a larger than normal font!**
 - In many environments (e.g., *xterm*, *VS Code*), we can adjust the font size with **Control+Shift+“+”** and **Control+“-”**
 - Or (e.g., *emacs*) hold down **Control** key and use mouse wheel
- **Long shell prompts** make reading your shell session difficult
 - Use **PS1='\$ '** or **PS1='# '**
- **Low contrast** color themes are difficult to read; change this if you can
- Turn on **line numbering** in your editor
 - In *vim* use: **:set number**
 - In *emacs* use: **M-x display-line-numbers-mode <RETURN>**
 - M-x means **Left-Alt+x**
- For collaborative editing, **relative line-numbering is evil....**
 - In *vim* use: **:set nornu**
 - In *emacs*, the following should suffice:

```
M-: (display-line-numbers-mode) <RETURN>
M-: (setq display-line-numbers 'absolute) <RETURN>
```

- M-: means **Left-Alt+Shift+:**

man7.org

Using *tmate* in in-person practical sessions

In order to share an X-term session with others, do the following:

- Enter the command *tmate* in an X-term, and you'll see the following:

```
$ tmate
...
Connecting to ssh.tmate.io...
Note: clear your terminal before sharing readonly access
web session read only: ...
ssh session read only: ssh S0mErAnD0m5Tr1Ng@lon1.tmate.io
web session: ...
ssh session: ssh S0mEoTheRrAnD0m5Tr1Ng@lon1.tmate.io
```

- Share last “ssh” string with colleague(s) via Slack or another channel
 - Or: “ssh session read only” string gives others read-only access
- Your colleagues should paste that string into an X-term...
- Now, you are sharing an X-term session in which anyone can type
 - Any “mate” can cut the connection to the session with the 3-character sequence **<ENTER> ~ .**
- To see above message again: *tmate show-messages*

man7.org

Booting to cgroups v2

- **In preparation for the following exercises**, if necessary reboot your system to use cgroups v2 only, as follows...
- First, check whether your system is already booted to use cgroups v2 only:

```
$ grep cgroup2 /proc/mounts          # Is there a v2 mount?
cgroup2 /sys/fs/cgroup cgroup2 ...
$ grep cgroup /proc/mounts | grep -v name= | grep -vc cgroup2
0                                     # 0 == no v1 controllers are mounted
```

- If there is a v2 mount, and no v1 controllers are mounted, then you do not need to do anything further; otherwise:
- From the GRUB boot menu, you can boot to cgroups v2-only mode by editing the boot command (select a GRUB menu entry and type “e”). In the line that begins with “**linux**”, add the following parameter:

```
systemd.unified_cgroup_hierarchy
```

man7.org

Exercises

- 1 In this exercise, we create a cgroup, place a process in the cgroup, and then migrate that process to a different cgroup.

- Create two subdirectories, `m1` and `m2`, in the cgroup root directory (`/sys/fs/cgroup`).
- Execute the following command, and note the PID assigned to the resulting process:

```
# sleep 300 &
```

- Write the PID of the process created in the previous step into the file `m1/cgroup.procs`, and verify by reading the file contents.
- Now write the PID of the process into the file `m2/cgroup.procs`.
- Is the PID still visible in the file `m1/cgroup.procs`? Explain.
- Try removing cgroup `m1` using the command `rm -rf m1`. Why doesn't this work?
- If it is still running, kill the `sleep` process and then remove the cgroups `m1` and `m2` using the `rmdir` command.

man7.org

Outline

20	Cgroups: Introduction	20-1
20.1	Preamble	20-3
20.2	What are control groups?	20-9
20.3	An example: the <code>pids</code> controller	20-16
20.4	Creating, destroying, and populating a cgroup	20-20
20.5	Exercises	20-28
20.6	Enabling and disabling controllers	20-34
20.7	Exercises	20-49
20.8	Appendix: Systemd and cgroups	20-53

Enabling and disabling controllers

- Each cgroup v2 directory contains two files:
 - `cgroup.controllers`: lists controllers that are **available** in this cgroup
 - `cgroup.subtree_control`: used to list/modify set of controllers that are **enabled** in this cgroup
 - Always a subset of `cgroup.controllers`
- Together, these files allow different controllers to be managed to **different levels of granularity** in v2 hierarchy

Available controllers: `cgroup.controllers`

```
$ cat /sys/fs/cgroup/cgroup.controllers
cpuset cpu io memory hugetlb pids rdma misc
```

- `cgroup.controllers` lists the controllers that are available in a cgroup
- Certain “automatic” controllers are always available in every cgroup, and are not listed in `cgroup.controllers`
 - `devices`, `freezer`, `network`, `perf_event`

Available controllers: `cgroup.controllers`

```
$ cat /sys/fs/cgroup/cgroup.controllers
cpuset cpu io memory hugetlb pids rdma misc
```

- A **controller may not be available** because:
 - Controller is **not enabled in parent cgroup**
 - (Does not apply for “automatic” controllers)
 - The same controller is already in use in cgroups v1
 - Cgroups v1 and v2 can coexist, but a controller can be used in only one version
 - Kernel was built without support for that controller
 - Controller was disabled at boot time
 - Using the boot option `cgroup_disable=name[,...]`

Enabling controllers: `cgroup.subtree_control`

- `cgroup.subtree_control` is used to show or modify the set of controllers that are enabled in a cgroup:

```
# cd /sys/fs/cgroup/
# cat cgroup.subtree_control
cpu io memory pids
```

- Set of controllers enabled in root cgroup will depend on distro and `systemd` configuration and version
- Contents of `cgroup.subtree_control` are always a subset of `cgroup.controllers`
 - I.e., can't enable controller that is not available in a cgroup
- Controllers are enabled/disabled by writing to this file:

```
# echo '+cpuset' > cgroup.subtree_control # Enable a controller
# cat cgroup.subtree_control
cpuset cpu io memory pids
# echo '-cpuset' > cgroup.subtree_control # Disable a controller
# cat cgroup.subtree_control
cpu io memory pids
```

Enabling controllers: `cgroup.subtree_control`

- Enabling a controller in `cgroup.subtree_control`:
 - Allows resource to be **controlled in child cgroups**
 - **Causes controller-specific attribute files to appear in each child directory**
- Attribute files in child cgroups are **used by process managing parent cgroup** to manage resource allocation into child cgroups
 - This is a significant difference from cgroups v1

`cgroup.subtree_control` example

- Review situation in root cgroup:

```
# cd /sys/fs/cgroup/  
# cat cgroup.controllers  
cpuset cpu io memory hugetlb pids misc  
# cat cgroup.subtree_control  
cpu io memory pids
```

- Create a small subhierarchy:

```
# mkdir -p grp_x/grp_y
```

- Controllers available in `grp_x` are those that were enabled at level above; no controllers are enabled in `grp_x`:

```
# cat grp_x/cgroup.controllers  
cpu io memory pids  
# cat grp_x/cgroup.subtree_control           # Empty...
```

- Consequently, no controllers are available in `grp_y`:

```
# cat grp_x/grp_y/cgroup.controllers           # Empty...
```

cgroup.subtree_control example

- List `cpu.*` files in `grp_y`:

```
# cd /sys/fs/cgroup/grp_x
# ls grp_y/cpu.*
grp_y/cpu.pressure  grp_y/cpu.stat
```

- (These two files show CPU-related statistics and are present in every cgroup)
- Enabling `cpu` controller in parent cgroup (`grp_x`) causes controller interface files to appear in child (`grp_y`) cgroup:

```
# echo '+cpu' > cgroup.subtree_control
# ls grp_y/cpu.*
grp_y/cpu.idle      grp_y/cpu.max.burst  grp_y/cpu.stat
grp_y/cpu.weight.nice  grp_y/cpu.max        grp_y/cpu.pressure
grp_y/cpu.weight
```

man7.org

cgroup.subtree_control example

- After enabling controller in parent cgroup, we can limit resources in child cgroup...
- Set hard CPU limit of 50% in child cgroup (`grp_y`):

```
# echo '50000 100000' > grp_y/cpu.max
```

- In another window, we start a program that burns CPU time and displays statistics; and we move it into `grp_y`:

```
# echo 6445 > grp_y/cgroup.procs    # 6445 is PID of burner process
```

- In the other terminal, we see:

```
$ ./cpu_burner
[6445] %CPU = 99.86
[6445] %CPU = 99.83
...
[6445] %CPU = 83.52
[6445] %CPU = 50.00
[6445] %CPU = 50.00
...
```

man7.org

Managing controllers to differing levels of granularity

- A controller is **available in child** cgroup only if it is **enabled in parent** cgroup:

```
# cat cgroup.controllers
cpuset cpu io memory hugetlb pids
# cat cgroup.subtree_control
cpu memory pids
# cat grp1/cgroup.controllers
cpu memory pids
```

- **cpuset**, **io**, and **hugetlb** are not available in **grp1**
- In **grp1**, none of the available controllers is initially enabled, so no controllers are available at next level:

```
# cat grp1/cgroup.controllers
cpu memory pids
# cat grp1/cgroup.subtree_control      # Empty
# mkdir grp1/{grp10,grp11}             # Make grandchild cgroups
# cat grp1/grp2/cgroup.controllers     # Empty
```

man7.org

Managing controllers to differing levels of granularity

- If we enable **cpu** in **grp1**, it becomes available at next level

```
# echo '+cpu' > grp1/cgroup.subtree_control
# cat grp1/grp10/cgroup.controllers
cpu
```

- And **cpu** interface files appear in **grp1/{grp10,grp11}**
- Here, **cpu** is being managed at finer granularity than **memory**
 - We can make distinct **cpu** allocation decisions for processes in **grp10** vs processes in **grp11**
 - But we can't make distinct **memory** allocation decisions
 - **grp10** and **grp11** will share **memory** allocation from **grp1**
- We **did this by design** (so we can manage different resources to different levels of granularity):
 - We want distinct CPU allocations in **grp10** and **grp11**
 - We want **grp10** and **grp11** to share a memory allocation

man7.org

Top-down constraints

- Child cgroups are always subject to any resource constraints established in ancestor cgroups
 - $\Rightarrow$ Descendant cgroups can't relax constraints imposed by ancestor cgroups
- If a controller is disabled in a cgroup (i.e., not present in `cgroup.subtree_control`), it cannot be enabled in any descendants of the cgroup

No internal tasks rule

- Cgroups v2 enforces a rule often expressed as: “a cgroup can't have both child cgroups and member processes”
 - I.e., only leaf nodes can have member processes
 - The “no internal tasks” rule
- But the rule more precisely is:
 - A cgroup can't both:
 - distribute a resource to child cgroups (i.e., enable controllers in `cgroup.subtree_control`), **and**
 - have member processes

No internal tasks rule

- Revised statement: “A cgroup can’t both distribute resources and have member processes”
- Conversely (1):
 - A cgroup **can** have member processes and child cgroups...
 - **if** it does not enable controllers for child cgroups
- Conversely (2):
 - If cgroup has child cgroups and processes, the processes must be moved elsewhere before enabling controllers
 - E.g., processes could be moved to child cgroups

No internal tasks rule

Further details on the no internal tasks rule:

- The root cgroup is (necessarily) an exception to this rule
- The rule is irrelevant for “automatic” controllers
 - Because those controllers (e.g., **freezer**, **devices**) are always available (i.e., don’t need to be enabled)
-  The rule changed for certain controllers in Linux 4.14
 - (The so-called “threaded controllers”)

Outline

20	Cgroups: Introduction	20-1
20.1	Preamble	20-3
20.2	What are control groups?	20-9
20.3	An example: the <code>pids</code> controller	20-16
20.4	Creating, destroying, and populating a cgroup	20-20
20.5	Exercises	20-28
20.6	Enabling and disabling controllers	20-34
20.7	Exercises	20-49
20.8	Appendix: Systemd and cgroups	20-53

Exercises

- ❶ This exercise demonstrates that resource constraints apply in a top-down fashion, using the cgroups v2 `pids` controller.
 - To simplify the following steps, change your current directory to the cgroup root directory (`/sys/fs/cgroup`).
 - Create a child and grandchild directory in the cgroup filesystem and enable the PIDs controller in the root directory and the first subdirectory:

```
# mkdir xxx
# mkdir xxx/yyy
# echo '+pids' > cgroup.subtree_control
# echo '+pids' > xxx/cgroup.subtree_control
```

- Set an upper limit of 10 tasks in the child cgroup, and an upper limit of 20 tasks in the grandchild cgroup:

```
# echo '10' > xxx/pids.max
# echo '20' > xxx/yyy/pids.max
```

Exercises

- In another terminal, use the supplied `cgroups/fork_bomb.c` program.

```
fork_bomb <num-children> [<child-sleep>]
# Default:      0          300
```

Run the program with the following command line, which (after the user presses *Enter*) will cause the program to create 30 children that sleep for (the default) 300 seconds:

```
$ ./fork_bomb 30
```

- The parent process in the `fork_bomb` program prints its PID. Return to the first terminal and place the parent process in the grandchild `pids` cgroup:

```
# echo parent-PID > xxx/yyy/cgroup.procs
```

- In the second terminal window, press *Enter*, so that the parent process now creates the child processes. How many children does it successfully create?

man7.org

Exercises

- 2 This exercise demonstrates what happens if we try to enable a controller in a cgroup that has member processes.

- Under the cgroup root directory, create a new cgroup named `child`, and enable the `memory` controller in the root cgroup:

```
# cd /sys/fs/cgroup          # or: cd /sys/fs/cgroup/unified
# mkdir child
# echo '+memory' > cgroup.subtree_control
```

- Start a process running `sleep`, and place its into the `child` cgroup:

```
# sleep 1000 &
# echo $! > child/cgroup.procs
```

- What happens if we now try to enable the `memory` controller in the `child` cgroup via the following command?

```
# echo '+memory' > child/cgroup.subtree_control
```

- Does the result differ if we reverse the order of the preceding steps (i.e., enable the controller, then place a process in the cgroup)?

man7.org

Outline

20	Cgroups: Introduction	20-1
20.1	Preamble	20-3
20.2	What are control groups?	20-9
20.3	An example: the <code>pids</code> controller	20-16
20.4	Creating, destroying, and populating a cgroup	20-20
20.5	Exercises	20-28
20.6	Enabling and disabling controllers	20-34
20.7	Exercises	20-49
20.8	Appendix: Systemd and cgroups	20-53

Systemd slices

- Systemd makes heavy use of cgroups
 - And provides a CLI for managing cgroups
- Organizes cgroups into **slices**—(sub)hierarchies of related cgroups
 - Slices are used to organize *services*, *scopes*, and other slices
- Systemd manages cgroups in two principal **slices**:
 - `system.slice`: cgroups used to manage system services
 - `user.slice`: cgroups used to manage user sessions and processes

Systemd and cgroups

- In the systemd model, processes are grouped in “units”, with associated cgroups
- Units are either:
 - **Persistent**: preconfigured units created on system boot, according to specifications in unit files
 - **Transient**: units created on-the-fly to run commands; disappear on command termination

Systemd services and scopes

- A **service** is a daemon or long-running process launched by systemd
 - Service is started and managed by systemd
 - Characteristics of service are defined via a unit file
 - Placed in cgroup with name suffixed by “.service”
- A **scope** is a cgroup subhierarchy for managing externally created processes
 - I.e., used for a set of processes not created directly by systemd
 - E.g., processes started by a window manager, interactive user session, a web browser, or [systemd-run](#)
 - No associated unit file; instead created programmatically via systemd’s D-Bus API
 - Placed in cgroup with name suffixed by “.scope”

systemd-run: run program in a systemd transient unit

- *systemd-run* runs a command in a new transient unit:

```
$ sudo systemd-run --scope -p CPUQuota=50% lsp/timers/cpu_burner
Running as unit: run-r362eae10dcc14fe184f224ef506b88cd.scope;
invocation ID: 2b42484dbbd2470eb7c53dabb8608b5a
[2149503] %CPU = 51.41 (0)
[2149503] %CPU = 49.84 (1)
[2149503] %CPU = 49.94 (2)
```

- Displays a *run unit identifier* we can use in other commands
- *--scope* runs command in a "scope" unit, rather than a "service" unit
 - Main purpose here: associates run unit with terminal, so we can see *stdout*
- *-p* is used to set a resource limit for cgroup
 - Can be specified multiple times, to set multiple limits
 - *systemd.resource-control(5)* documents the various limits that can be set

systemctl status: view status of a systemd unit

- *systemctl status* shows info about a systemd unit:

```
$ systemctl status run-r362eae10dcc14fe184f224ef506b88cd.scope
● run-r362eae10dcc....scope - /home/mtk/lsp/timers/cpu_burner
   Loaded: loaded (/run/systemd/transient/run-r362eae....scope; transient
   Transient: yes
   Active: active (running) since Sat 2025-03-01 10:55:07 NZDT; 35min ago
  Invocation: 2b42484dbbd2470eb7c53dabb8608b5a
     Tasks: 1 (limit: 76492)
    Memory: 156K (peak: 548K)
       CPU: 3.189s
    CGroup: /system.slice/run-r362eae10dcc14fe184f224ef506b88cd.scope
             └─2149503 /home/mtk/lsp/timers/cpu_burner
```

- Includes number of tasks, CPU + memory usage, and cgroup

systemctl set-property: set resource limits

- *systemctl set-property* allows us to change limits associated with a systemd unit:

```
$ sudo systemctl set-property run-r362eae10dcc[...] CPUQuota=20%
```

- Returning to terminal window where *cpu_burner* is running, we see:

```
[2149503] %CPU = 20.30 (13)
[2149503] %CPU = 19.96 (14)
[2149503] %CPU = 20.07 (15)
```

- Can set multiple limits in a single command:

```
$ sudo systemctl set-property run-r362eae[...] CPUQuota=20% MemoryMax=500K
```

- *systemd.resource-control(5)*

Other *systemctl* commands

- *systemctl freeze*, *systemctl thaw*: freeze and thaw a unit
- *systemctl stop*
 - Graceful termination of a unit
- *systemctl kill*
 - A more forceful termination of a unit
